A
COMPLETE SET OF
NAUTICAL TABLES,

CONTAINING *ALL* THAT ARE

Requisite,

WITH THE NAUTICAL ALMANAC, IN KEEPING A SHIP'S RECKONING

AT SEA,

AND IN ASCERTAINING THE LATITUDE AND LONGITUDE BY

CELESTIAL OBSERVATIONS;

INCLUDING A NEW, ACCURATE, AND EXTENSIVE TABLE OF THE
LATITUDES AND LONGITUDES OF THE PRINCIPAL PORTS,
HARBOURS, CAPES, ETC. IN THE WORLD,

WITH SEVERAL OTHER

NEW AND IMPROVED TABLES.

TO WHICH IS PREFIXED,
A COPIOUS EXPLANATION OF THE TABLES;

LIKEWISE

Astronomical Problems

FOR FINDING THE

L A T I T U D E

BY DOUBLE ALTITUDES OF THE SUN, AND THE

LONGITUDE

BY LUNAR OBSERVATIONS, AND BY A CHRONOMETER, OR TIME-KEEPER.

BY J. W. NORIE,

TEACHER OF NAVIGATION AND NAUTICAL ASTRONOMY.

London :

Printed for the AUTHOR, and for WILLIAM HEATHER, at the
NAVIGATION WAREHOUSE, Leadenhall-Street.

1803.

Entered at Stationer's Hall.

THIS COMPANIE

SET OF NAUTICAL TABLES,

For the Use of whose Officers it is principally designed,

IS BY PERMISSION,

And with the greatest Respect,

DEDICATED

By their most obedient

Humble Servant,

JOHN WILLIAM NORIE.

SIR,

THE Court of Directors of the East India Company, entertaining a very high Opinion of the Set of NAUTICAL TABLES, compiled by you, principally for the Company's Service, have permitted you to dedicate the same to the Court: and I have at the same Time to acquaint you, that they have agreed to subscribe for Forty Copies of the Work.

I am,

SIR,

Your most obedient Servant,

Wm. RAMSAY,

SECRETARY.

East-India-House,

the 7th July, 1803.

Mr. John William Norie.

SIR,

The Court of Directors of the
East India Company, entertaining a very high
Opinion of the Set of NAUTICAL TABLES compiled
by you, principally for the Company's Service, have
permitted you to dedicate the same to the Court;
and I have at the same time to acquaint you that
they have agreed to subscribe for Forty Copies of
the Work.

I am,

SIR,

Your most obedient Servant,

Wm. RAMSAY

SECRETARY

East India House,

the 7th July 1803

Mr. John William Norrie

PREFACE.

WHEN the infinite importance of Navigation, theoretical and practical, is taken into consideration, and the advantages resulting from it to mankind are duly appreciated, it cannot be matter of surprize that a subject in which their most essential temporal interests are involved should have called forth the exertions of the most eminent professional men in the production of the various Nautical Tables which have, from time to time, been presented to the public.

It may, however, without the imputation of want of candour be remarked, that though these productions have a just claim to merit, they are not wholly exempt from objection, as they have in general been very expensive, in many instances extremely erroneous, and at the same time inadequate to answer all the purposes of the practical Mariner.

For these reasons I have been induced to collect and compose a set of Tables adapted to obviate the disagreeable necessity of recurring to other Books, besides the Nautical Almanac, when making the calculations requisite to keep a Ship's Reckoning, and ascertaining the Latitude and Longitude at Sea by celestial Observations; so that these Tables will be of manifest advantage to the Practitioner, in saving him time, labour, and expence.

I do not by any means presume to offer, as a plea for the introduction of this Work to the public, a claim to superior professional merit, or arrogate a competition with those able Mathematicians whose labours have so powerfully tended to the advancement of knowledge in the science of Navigation; nevertheless, I humbly apprehend, that from the many years I have been in the habit of instructing Youth, and my long intercourse with intelligent and experienced Officers in the various Services, I have been enabled, from repeated observation and investigation, to form a competent judgment of what is most conducive to the main purposes of Navigation; of this I have endeavoured to avail myself in the following sheets, in which it has been my principal design to unite accuracy, neatness, and convenience.

With

With respect to accuracy, the primary object as indispensably requisite in the composition of a nautical Table, I have, in order to effect that particular as completely as possible, placed in a comparative view the most established different Authorities, and those parts in which variations were observed I have recomputed with the utmost assiduity and precision, and, in many instances, recalculated the whole Table; I have also been particularly attentive to the correction of the Press, in reading and revising the proof Sheets, aware of the inconvenience and embarrassment that might result to the practical Mariner from the slightest typographical error, which I have most studiously laboured to prevent.

Neatness and convenience, though but secondary considerations, are objects worthy of attention; I have therefore caused the Work to be printed on an excellent type and paper, and of a portable size:—In short, neither labour nor expence have been spared to render it deserving of public approbation, which it will ever be my highest ambition to obtain.

It is presumed that a copious Explanation, prefixed to the Tables, renders a review of them in this place unnecessary; I shall therefore only add, that I have, with the nicest discrimination, introduced all such Tables as appeared to me essential, and rejected those which I consider as unimportant in the practice of Navigation.

Though this Work is principally intended for those who are already skilled in Navigation, yet, as many of the rules in the Astronomical part are long, and liable to escape the memory of persons not in the constant practice of applying them, I have thought proper to subjoin such rules, illustrated by appropriate examples, as may remedy this defect, and at the same time instruct those who are not already initiated in the Science.

To this purpose I have given Mr. Douwes' Method of finding the Latitude by two Altitudes of the Sun, with Directions respecting the Times of Observation: likewise Rules for computing the Longitude by lunar Observations, in which I have introduced four Methods of clearing the Distance—the first of these is Mr. Dunthorne's; the second is derived from that of M. Borda, abridged by the Table of Logarithmic Differences; both requiring six places of figures; the third is similar to that given by Mr. Witchell, and requires only four places of figures; the fourth was invented by Mendoza Rios, Esq. and has the peculiar advantage of not requiring any distinction

of Cases, an inconvenience which prevails in the third, and, indeed, in every other, except the present, approximate Method. This manner of computing the two principal corrections has long since been communicated by Mr. Rios to several persons, and to the Royal Society, in a paper read 1796, and published in their Transactions, in Part the First, 1797. And here it may be proper to observe, that this Method has been given, in a mutilated state, in a recent publication on Navigation, from America, where it is asserted as being derived from that of Mr. Lyons, a mistake which the slightest acquaintance with the Mathematics will easily discover.

The Method of finding the Longitude at Sea by a Chronometer, or Time-keeper, being now much practised, particularly in the Honourable East India Company's Service, I have thought it proper to add Rules and Examples for that purpose: and I take this opportunity of recommending to persons using these delicately constructed machines, not to remove them when once secured on board Ship, as it is much to be apprehended that the alteration in their rate may, in a great measure, be attributed to want of care in this respect.

Having thus stated the outlines and design of this Work, I shall leave the Public to determine how far I have succeeded in my endeavours, assuring them that I shall consider my labours well bestowed if I have in the least contributed to facilitate, and thereby extend, the practical part of Navigation.

J. W. NORIE.

Naval Academy,
Leadenhall-Street.

EXPLANATION AND USE

OF THE

T A B L E S.

TABLES I. and II.

Difference of Latitude and Departure for Points and Degrees.

THESE Tables are of very extensive use in Navigation, affording an easy and expeditious method of solving all problems in right angled plane trigonometry, and consequently applicable to the various sailings, but particularly useful in working a traverse, from whence they obtain the name of *Traverse Tables*.

Table I. contains the difference of latitude and departure, answering to distances not exceeding 300, and for courses to every quarter point of the compass. Table II. is of the same nature and extent, but for courses consisting of whole degrees. The courses are set down at the top of the pages when they do not exceed 4 points or 45 degrees, and at the bottom when they are greater than these quantities: the distances are regularly arranged in the columns marked *Dist.* with their corresponding difference of latitude and departure immediately opposite in the columns marked *Lat.* and *Dep.* but it must be carefully observed, that when the course is less than 4 points or 45 degrees, these must be taken out as marked at the top, and when more, as noted at the bottom of the pages.

Now as the difference of latitude and departure answering to any given course and distance, are found opposite the distance in that page of the table which contains the course, if therefore any two of the four things, viz. the course, distance, difference of latitude, and departure, be given, and those two be found together in the tables, the other two things will be found in their respective places on the same page. In like manner the parts of any right angled plane triangle may be found, (provided two of them, exclusive of the right angle, be given) by taking out the hypotenuse as a *Distance*, the perpendicular in the *Lat.* column, the base in the *Dep.* column, and the angle opposite to it as a course: hence when these tables are applied in parallel or middle latitude sailing, the Co. lat. or Co. mid. lat. is taken as a course, the departure or meridional distance is found in the *Dep.* column, and the difference of longitude in the *Dist.* column; in Mercator's Sailing the meridional difference of latitude is taken

out in the *Lat.* column, and the difference of longitude in the *Dep.* column.

When the given numbers exceed the limits of the table, any aliquot part, as a half, third, fourth, &c. is to be taken; and those found corresponding are to be doubled, trebled, &c. that is, multiplied by the same figure that the given number is divided by.

TABLE III.

Meridional Parts.

This table is used in resolving problems by Mercator's sailing, and in constructing charts on Mercator's Projection. The meridional parts are to be taken out for the degrees answering to the given latitude at the top or bottom, and for the minutes at either side column. Thus, the meridional parts corresponding to the latitude $49^{\circ} 57'$ are 3470.

TABLE IV.

Mean Refraction.

This table contains the refraction of the heavenly bodies, in minutes and seconds, at a mean state of the atmosphere, and corresponding to their apparent altitudes. This correction is always to be subtracted from the apparent altitude of the object. Ex. The mean refraction to the apparent altitude $10^{\circ} 50'$ is $4' 51''$.

TABLE V.

Depression; or Dip of the Horizon.

This correction arises from the elevation of the observer above the surface of the sea, whereby the visible horizon, or that seen by the observer, is below the true; and consequently altitudes taken with the quadrant are too great by a quantity to be taken out from this table with the height of the observer's eye in feet, to be subtracted from the observed altitude. Ex. The dip for 20 feet is $4' 17''$.

TABLE VI.

The Sun's Parallax in Altitude.

The sun's parallax in altitude is exhibited in this table to every tenth degree, and is always additive to the apparent altitude.

TABLE VII.

The Moon's Augmentation.

The moon's horizontal semidiameter, as given in the Nautical Almanac, is to be increased by a number of seconds, called the augmentation, taken out from this table nearest answering to his altitude, in order to give the true semidiameter.

TABLE VIII.

Dip of the Sea at different Distances from the Observer.

When that part of the horizon immediately under the sun is obstructed by land, and the observer is nearer the shore than five or six miles, then if the object be brought down to the line separating the sea and land, the dip will exceed that shewn in Table V, which is calculated for an open and unobstructed horizon, and will increase as the distance from the land diminishes. In this case, the dip is to be taken from the present table with the height of the eye at the top, and the distance estimated in miles in the side column.

TABLE IX.

Sun's Declination.

The sun's declination is contained in this table from the year 1802 to 1817 inclusive. It is to be taken out with the month at the top and the day in either side column, at the same time noting whether it be north or south as expressed at the top of each column. The declination being given in this table to the nearest minute, will in general be sufficiently exact for ascertaining the latitude at sea; but when greater precision is requisite, it must be taken from the Nautical Almanac, and corrected by Table XXI.

TABLE X.

To correct the Sun's Declination.

As the sun's declination in Table IX. is adapted to the meridian of Greenwich, when the ship is considerably to the eastward or westward, it should be corrected by a number of minutes taken from this table, placed at the bottom for that purpose, with the declination at the top and the nearest longitude in the side columns, to be added or subtracted as directed at the head of the table.

EXAMPLE.

Required the Sun's Declination at Noon on Sept. 18th, 1805, in Longitude 108° West.

Sun's Declination from Table IX. - $1^{\circ} 57'$ north.

Correction for longitude Table X. to be sub. — 7

Sun's true declination $1^{\circ} 50'$ north.

TABLE XI.

The Sun's right Ascension.

The sun's mean right ascension contained in this table is to be taken out with the month at the top, and the day in either side columns; it is sufficiently exact for ascertaining the time of an object's passing the meridian in order to obtain the latitude by its meridian altitude; but when greater accuracy is necessary, recourse must be had to the Nautical Almanac.

TABLE XII.

To find the Time of high Water.

The common method of finding the time of high water at any given place, being in many cases extremely erroneous, it is thought proper to insert this table, since, by its assistance, the time may be found within a few minutes, unless the tides should be greatly influenced by the winds. For this purpose, the time of the phase answering nearest to the given day, must be taken from page 1 of the Nautical Almanac, and reduced to the meridian of the given place by adding to it the longitude of the place in time, if it be east, or subtracting if west; then the difference between this reduced time and the noon of the given day being found in the table, with the phase at the top, will give a correction, which is to be applied to the time of high water at full and change, as the table directs, in order to give the approximate time of high water in the afternoon. Then by applying again the correction corresponding to the interval between the reduced time of the phase and that approximate time, the result will be the time of high water in the afternoon.

If the time of high water is required for the morning, the last interval must be increased by 12 hours when the given day falls before the nearest phase, or diminished by 12 hours when after the phase; then the corresponding correction applied as before, will give the time of high water in the morning.

EXAMPLE.

Required the Time of high Water at Lisbon, on Feb. 8th, 1805.

	D. h. m.
Time of moon's first quarter at Greenwich, by } Nautical Almanac	6 14 9
Longitude of Lisbon in time	— 37 W.
Time of moon's first quarter at Lisbon	6 13 32
Given day	8
Interval after first quarter	1 10 28
Correction for that interval by table	+ 6 53
Time of high water at Lisbon, full and change	2 15
Approximate time of high water	8 9 8
Reduced time of moon's first quarter	6 13 32
Interval after first quarter	1 19 36
Correction for that interval by table	+ 7 23
Time of high water at Lisbon, full and change	2 15
Time of high water at Lisbon Feb. 8th	9 38 P. M.
Interval after first quarter less 12 hours	1 7 36
Correction for that interval by table	+ 6 44
Time of high water at Lisbon, full and change	2 15
Time of high water at Lisbon Feb. 8th	8 59 A. M.

TABLE

TABLE XIII.

Amplitudes.

This table is intended to expedite the method of finding the variation of the compass by comparing the magnetic with the true amplitude: the latter is here given in degrees and minutes, and is to be found with the declination at the top and the latitude in the left side column: moreover, when the minutes of the latitude or declination are nearly 30, or half a degree, the mean of the amplitudes found for the two nearest degrees, will give the amplitude required, as shewn in the following examples.

EXAMPLE I.

What is the Sun's true Amplitude in Latitude $51^{\circ} 31' N.$ when the Declination is 8° .

True amplitude by table for lat. 51° and declination 8°	-	$12^{\circ} 47'$
- - - - lat. 52 and declination 8°	-	$13 \quad 4$
		$2)25 \quad 51$
Sun's true amplitude required	-	$12 \quad 55$

EXAMPLE II.

Required the Sun's true Amplitude in Latitude $34^{\circ} 5'$ when the Declination is $18^{\circ} 32'$.

True amplitude by table for lat. 34° and declination 18°	-	$21^{\circ} 53'$
- - - - lat. 34 and declination 19	-	$23 \quad 7$
		$2)45 \quad 0$
Sun's true amplitude required	-	$22 \quad 30$

EXAMPLE III.

On what Points of the Horizon does the Sun rise and set, in Latitude $57^{\circ} 56' N.$ when his Declination is $18^{\circ} 28' S.$

Sun's true amplitude for lat. 57° and declination 18°	-	$34^{\circ} 34'$
- - - lat. 57 and declination 19	-	$36 \quad 43$
- - - lat. 58 and declination 18	-	$35 \quad 40$
- - - lat. 58 and declination 19	-	$37 \quad 54$
		$4)144 \quad 51$
Sun's true amplitude required	-	$36 \quad 13$

Hence the sun rises E. $36^{\circ} 13' S.$ or S. E. $\frac{3}{4} E.$

and sets W. $36 \quad 13 S.$ or S. W. $\frac{3}{4} W.$

In the same manner the true amplitude of the moon, planets, or stars, may be found when their declination and the latitude are given.

TABLE XIV.

*Semidiurnal and Seminocturnal Arches,**for finding the Time of the rising and setting of the Sun, Moon, or Stars.*

This table exhibits half the time that a celestial object continues above the horizon when the latitude and declination are of the same name, or below, when they are of contrary names; usually called its semidiurnal and seminocturnal arches, from whence the time of its rising and setting may be computed; these are to be taken out with the latitude in either side column and the declination at the top; then the angle of meeting will point out the arch required, which, if the object be the sun, will be the time of its setting when the latitude and declination are of the same name, or of its rising when they are of contrary names; and this subtracted from 12 hours, will give the time of the sun's rising in the former case, and of its setting in the latter; double the time of his rising will be the length of the night, and double the time of his setting the length of the day.

EXAMPLE.

Required the time of the Sun's rising and setting, with the length of the day and night, in Latitude $51^{\circ} 31'$ N. when the declination is 20° N.

The time answering to lat. 51° and declin. 20° is	-	h. m.
- - - lat. 52 and declin. 20°	-	7 47
		7 51

2) 15 38

Time of sun's setting, because lat. and declin. are both N.	-	7 49
		12

Time of sun's rising	-	4 11
----------------------	---	------

Double the rising gives the length of the night	-	8 22
---	---	------

Double the setting gives the length of the day	-	15 38
--	---	-------

To find the time of a star's rising and setting, the time of its passing the meridian must be previously ascertained by subtracting the sun's right ascension from the star's right ascension, (increased by 24 hours if necessary) then the latitude and declination, when they are of the same name, will give the time the star takes in ascending from the horizon to the meridian, and descending from the meridian to the horizon; therefore, if these hours and minutes be subtracted from the time of its passage over the meridian, the remainder will be the time of its rising, and, if added, the sum will be the time of its setting.

But when the latitude and declination are of contrary names, the time found as above will be half the star's continuance under the horizon, consequently it is to be subtracted from 12 hours to give half the time of its continuance above the horizon, with which proceed as before.

EXAMPLE

EXAMPLE I.

At what time does the star Arcturus rise and set on June 1st, in latitude 51° North?

	h.	m.
Star's right ascension by Table XV.	14	7
Sun's right ascension June 1st by Table XI.	4	35
Time of the star's passing the meridian	9	32
Time answering to lat. 51° N. and star's declin. 20° N. is	7	47
Remainder gives the time of the star's rising	1	45
Sum gives the time of the star's setting	17	19 P.M.
	or	5 19 A.M.

EXAMPLE II.

At what time does the Star Regulus rise and set on May 10th, in latitude 33° South.

	h.	m.
Star's right ascension by table XV.	9	58
Sun's right ascension May 10th by Table XI.	3	7
Time of star's passing the meridian	6	51
Time answering to lat. 33° S. and star's declin. 13° N., subtracted from 12 hours, is	5	26
Remainder gives the time of the star's rising	1	25
Sum gives the time of the star's setting	12	17 P.M.
	or	0 17 A.M.

After the same manner the time of the rising and setting of the planets may be computed, observing to take out their declination and passage over the meridian from page IV. of the Nautical Almanac.

To find the rising and setting of the moon, the time of her passage over the meridian is to be taken from page VI. of the Nautical Almanac, to which the minutes from Table XVI. are to be applied, in order to obtain the time of its passing the meridian of the given place. Then the semidiurnal arch answering to the moon's declination (given in page VI. of the N. A.) and the latitude of the place, subtracted from the above reduced time, will give the approximate time of the moon's rising, or added thereto, will give that of setting. But as the moon changes her declination sometimes very rapidly, if greater accuracy is required it must be reduced to the approximate time of its rising or setting by Table XVIII. then the semidiurnal arch being again found and corrected by adding the minutes from Table XVI. corresponding thereto, and the daily variation of her passage over the meridian, the sum subtracted from or added to the reduced passage over the meridian, will give the time of her rising or setting.

EXAMPLE.

EXAMPLE.

Required the time of the Moon's rising at St. Helena in Lat. $15^{\circ} 55' S.$
and Long. $5^{\circ} 43' W.$ on July 10th 1805.

	h.	m.
In page VI. of the N. A. the time of the moon's passing the meridian of Greenwich is 11 h. 18 m. to which 1 minute (the number from Table XVI. answering to the daily variation and longitude) being added, gives the time of her passing the meridian of St. Helena	11	19
Time answering to lat. $16^{\circ} S.$ and moon's declin. $24^{\circ} S.$	6	29
Remainder gives the approximate time of moon's rising	4	50

The Moon's Declination at this time reduced to the Meridian of Greenwich by Table XVIII. is $24^{\circ} 22' South.$

	h.	m.
Time answering to lat. $16^{\circ} S.$ and declin. $24^{\circ} 22' S.$	6	30
Corr. from Tab. XVI. to 6 h. 30 m. and daily var. 48 m.	+	13
Semidiurnal arch	6	43
Reduced time of moon's passing the meridian	11	19
Time of moon's rising	4	36

It must be understood that the above methods are only approximations, and may deviate two or three minutes from the truth; but it is presumed they will be found sufficiently exact for nautical purposes.

The semidiurnal and seminocturnal arches may be found independent of this table, by adding together the log. tangents of the given latitude and declination, which sum will be the log. sine of an arch in degrees, &c. to be reduced into time and increased by 6 hours.

TABLE XV.

The right Ascensions and Declinations of the principal fixed Stars.

The right ascensions and declinations of 60 of the principal stars contained in this table are computed for the beginning of the year 1800, with their annual variations in seconds and decimal parts of a second. If their places are required for any time subsequent to the year 1800, the annual variation both in right ascension and declination must be multiplied by the number of years and parts of a year elapsed since that time, and the product will be the variation from the beginning of 1800 to the given time. This variation must always be added to the right ascension for 1800, but the variation in declination is additive or subtractive according as the sign $+$ or $-$ is prefixed to the annual variation; then the sum or remainder will be the right ascension and declination for subsequent years. But if the place of a star be required for any time preceding 1800, the variation in right ascension must be subtracted from that in the table, and the variation in declination applied contrary to the sign set against it.

EXAMPLE.

EXAMPLE.

Required the right Ascension and Declination of the Star Arcturus in June 1805.

From the beginning of 1800 to June 1805, there are about $5\frac{1}{2}$ years.

	h.	m.	s.
R. A. of Arcturus (in time) for the beginning of 1800	14	6	32
Annual variation $+ 2^s.72$ multiplied by $5\frac{1}{2}$ gives	+		15
R. A. of Arcturus for June 1805	14	6	47
Declination of Arcturus for the beginning of 1800	20	13	45 N.
Annual variation $- 19''.1$ multiplied by $5\frac{1}{2}$ gives	—	1	45
Declination of Arcturus for June 1805	20	12	0 N.

TABLE XVI.

To reduce the Time of the Moon's Passage over the Meridian of Greenwich to the Time of his Passage over any other Meridian.

The daily variation of the moon's passing the meridian is the excess of time above 24 hours that elapses till her return to the same, and this is found by taking the difference between her passing the meridian of Greenwich on a given day (from page VI. in the N. A.) and the preceding, if the longitude of the place be east, or that and the following if the longitude be west.

Now as the moon is constantly advancing to the eastward in the heavens, she will therefore pass any meridian to the eastward of Greenwich sooner in the day, or a meridian to the westward later, than she does that of Greenwich by a certain number of minutes, which is to the daily variation as the given longitude of the place is to 360° , and on this principle the table is constructed.

The table is to be entered with the daily variation at the top and the longitude of the place in the left side column; then the minutes corresponding to these being added to the time of the moon's passing the meridian of Greenwich, if the longitude be west, or subtracted if east, the sum or remainder will be the time of her passing the meridian of the place.

EXAMPLE.

At what Time will the Moon pass the Meridian of Calcutta in Longitude $88^\circ 28'$ E. on July 3d, 1805?

	h.	m.
Moon's passage over the Meridian of Greenwich, July 3d, by the Nautical Almanac	5	43
Correction corresponding to daily var. 45 m. and long. $88^\circ 28'$	—	11
Time of moon's passing the meridian of Calcutta July 3d	5	32

This table is likewise useful in computing the time of the moon's rising and setting, as shewn in the explanation to Table XIV.

TABLE XVII.

To correct the mean Refraction.

The refractions contained in Table IV. being adapted to a mean state of the atmosphere, that is, when the thermometer stands at 50° and the barometer at 29.6 inches, if it deviates from this weight and temperature, and accuracy is required, it will be necessary, especially in low altitudes, to correct the mean refraction by the seconds contained in this table, which are to be taken out with the apparent altitude in the side column, and the heights of the thermometer and barometer at the top and bottom, to be added or subtracted as expressed at the top of the columns.

EXAMPLE.

Let the apparent Altitude be 5° . the height of the Thermometer 72° . and that of the Barometer 29.2: required the true refraction.

Mean refraction by Table IV. to 5° alt.	-	9' 54"
Corr. for alt. 5° and 72° height of thermometer	- 31"	} - 40
alt. 5° and 29.2 height of barometer	- 9	
True refraction required		9 14

The true refraction may be found by adding to the logarithm of the difference between the height of the thermometer and 450, the log. of the height of the barometer, the logarithm of the mean refraction in seconds, and the constant logarithm 5.92665; the sum of these four logs. rejecting 10 in the index, will be the log. of the true refraction in seconds. The preceding Example is thus worked by logarithms:

450 — 72° height of thermometer is 378	log. 2.57749
Height of barometer - - - 29.2	log. 1.46538
Mean refraction 9' 54" or - - - 594	log. 2.77379
Constant	log. 5.92665

True refraction required 554" or 9' 14" log. 2.74331

TABLE XVIII.

To reduce the Moon's Declination to any given Meridian, and to any Time under that Meridian.

This table contains the proportional part of the variation of the moon's declination in twelve hours, answering to a given time from noon or midnight and to a given longitude; it facilitates the reduction of the moon's declination, as given in page VI. of the Nautical Almanac, and is to be entered with the variation of the moon's declination in 12 hours at the top, and with the longitude and time from the preceding noon or midnight in the side columns: the corrections thus found being applied to the declination for the preceding noon or midnight, as pointed out at the head of the table, will give the moon's reduced declination.

EXAMPLE.

EXAMPLE I.

Required the Moon's Declination on July 5th, 1805, at 9 h. 25 m.
Greenwich Time.

Moon's declination July 5th at Noon by Nautical Almanac	-	17° 17' S.
Corr. answering to var. 1° 54' and time 9 h. 25 m.	-	+ 1 29
Moon's reduced declination		18 46 S.

EXAMPLE II.

What will be the Moon's Declination on Feb. 11th, 1805, at 15 h. 45 m.
in longitude 75° West?

Moon's declination Feb. 11th at midnight by Naut. Alm.	-	20° 16' N.
Corr. to var. 2° 14' and long. 75° W.	-	- 56
var. 2 14 and time from midnight 3 h. 45 m.	-	43
Moon's reduced declination		18 37 N.

TABLE XIX.

To reduce Longitude into Time and the contrary.

This table is intended to facilitate the reduction of degrees, &c. of longitude into time, or of hours, &c. into longitude. The method of using it will best appear by inspecting the following examples.

EXAMPLE I.

Required the Time answering to 43° 13' 42" of longitude.

	°	'	"	h.	m.	s.	t.
Time answering to	42	0	0	is	2	48	0
-		13	0	-		52	0
-			42	-		2	48

Hence the time answering to 42 13 42 - 2 48 54 48

EXAMPLE II.

Required the Degrees, &c. corresponding to 7 h. 6 m. 48 s.

	h.	m.	s.	°	'
Long. corresponding to	7	4	0	is	106
-		2	48	-	42

Hence the long. corresponding to 7 6 48 - 106 42

TABLE XX.

For finding the Distance of terrestrial Objects at Sea.

When the eye is elevated above the surface of the adjacent land or water, we not only see surrounding objects more distinctly, but also see those which are more remote the higher we advance. Now, although the irregularity of the surface of the land will not admit of any one rule that will give the distance to which objects may be seen at different elevations, yet at sea, where the curvature of the water is uniform, those distances may be easily computed by means of this table, in which the distances

are exhibited in nautical miles* and decimal parts, answering to the height of the eye or that of the given remote object, allowance having been made for terrestrial refraction.

EXAMPLE.

Being at the Mast-head looking out for Land, and elevated 130 Feet above the Surface of the Sea, I discovered the top of a Light-house in the Horizon, whose height is known to be 300 Feet: required my distance from the Light-house.

In the table opposite 130 feet is	-	-	-	-	miles.
-	-	-	-	-	13.1
-	-	-	-	-	19.9
Sum gives the distance of the ship from the light-house					33.0

TABLE XXI.

To reduce the Sun's Declination to any given Meridian and to any Time under that Meridian.

This table contains the corrections to be applied to the sun's declination as given in the Nautical Almanac, which is computed for noon at Greenwich, when it is required for noon at any other meridian, or to any given time of the day: it is to be entered with the declination for the nearest noon at the top, as found in page II. of the Nautical Almanac, and the longitude or time from noon in the side columns; corresponding to these will be found the minutes and seconds to be applied to the above declination by addition or subtraction, as directed at the head of the table; that is, when the declination is increasing, the corrections are to be added in west longitude or afternoon, and to be subtracted in east longitude or before noon; but when the declination is decreasing, the corrections are to be subtracted in west longitude or afternoon, and to be added in east longitude or before noon.

When the declination and longitude or time from noon are not nearly found in the table, proportional parts must be used if great exactness is required.

It must be observed that this table is subject to an error of a few seconds from the sun's unequal motion in the ecliptic, but it is nevertheless sufficiently exact for observations taken at sea.

EXAMPLE I.

Required the Sun's Declination at Noon on Sept. 18th, 1805, in Longitude $105^{\circ} 15'$ West.

Sun's declination at Greenwich by Nautical Almanac	-	-	-	-	$1^{\circ} 57' 27''$ N.
Correction for Longitude	-	-	-	-	6 51
Sun's reduced declination	-	-	-	-	$1^{\circ} 50' 36''$ N.

* A nautical mile contains 6080 feet.

EXAMPLE II.

Required the Sun's Declination on June 1st, 1805, at 4 h. 20 m. Greenwich Time.

Sun's declination at Noon by Nautical Almanac	-	22°	2'	26" N.
Correction for time	-	+	1	33
Sun's reduced declination	-	22	3	59 N.

EXAMPLE III.

What will be the Sun's Declination on Nov. 13th, 1805, at 4 h. 40 m. in longitude 80° 45' West?

Sun's declination at noon by Nautical Almanac	-	17°	56'	48" S.
Correction for longitude	-	+	3	30
- - time after noon	-	+	3	3
Sun's reduced declination	-	18	3	21 S.

EXAMPLE IV.

Required the Sun's Declination April 25th, 1805, at 19 h. 36 m. in Longitude 71° 50' West.

Sun's declination April 26th by Nautical Almanac	-	13°	27'	36" N.
Correction for longitude 71° 50' west	-	+	3'	55" }
- - time before noon 4 h. 24 m.	-	-	3	35 }
				+ 20
Sun's reduced declination	-	13	27	56 N.

It will sometimes happen, when the sun is near the equinoxes, that the correction for longitude and time will exceed the declination; in this case, if the correction is subtractive, the declination is to be taken from it, and the remainder will be the reduced declination of a contrary name to that taken from the almanac.

EXAMPLE V.

What will be the Sun's Declination on March 20th, 1805, at 18 h. 12 m. and in longitude 120° East?

Sun's declination March 21st by Nautical Almanac	-	0°	10'	55" N.
Correction for longitude 120° east	-	-	7'	51" }
- - time before noon 5 h. 48 m.	-	-	5	41 }
				- 13 32
Sun's reduced declination	-	0	2	37 S.

TABLE XXII.

To reduce the Sun's right Ascension to any given Meridian and to any Time under that Meridian.

By this table the sun's right ascension, taken out for the nearest noon from page II. of the Nautical Almanac, may be reduced to any given time or place. It is to be entered with the right ascension at the top and the given longitude or time from noon in the side columns: the corrections

tions corresponding to these being added to the right ascension as above, if the longitude be west or the time afternoon, but subtracted if the longitude be east or the time before noon; the result will be the sun's reduced right ascension.

EXAMPLE I.

Required the Sun's right Ascension at Noon May 8th, 1805, in longitude 85° West.

		h.	m.	s.
Sun's right ascension by Nautical Almanac	-	2	59	42
Correction for longitude 85° west	-	+		54
Sun's reduced right ascension	-	3	0	36

EXAMPLE II.

What will be the Sun's right ascension on October 10th, 1805, at 10 h, 50 m. Greenwich time?

		h.	m.	s.
Sun's right ascension at noon by Nautical Almanac		13	1	38
Correction for time afternoon 10 h. 50 m.	-	+	1	39
Sun's reduced right ascension	-	13	3	17

EXAMPLE III.

What will be the Sun's right Ascension on Nov. 25th, 1805, at 9 h. 40 m, in longitude $49^{\circ} 25'$ east?

		h.	m.	s.
Sun's right ascension at noon by Nautical Almanac	-	16	3	6
Correction for longitude $49^{\circ} 25'$ east	-	-	0	35
- - time after noon 9 h. 40 m.	+	1	43	
Sun's reduced right ascension	-	16	4	14

EXAMPLE IV.

Required the Sun's right Ascension on July 12th, 1805, at 14 h. 10 m. in longitude 120° west.

		h.	m.	s.
Sun's right ascension July 13th by Nautical Almanac	-	7	28	54
Correction for longitude 120° west	-	+	1	21
- - time before noon 9 h. 50 m.	-	-	1	40
Sun's reduced right ascension	-	7	28	35

TABLE XXIII.

Logarithmic Sines, Tangents, and Secants, to every Point and Quarter Point of the Compass.

This table is useful when the logarithmic sine, tangent, or secant of a ship's course is required to points of the compass; it is to be entered with the points in the left side, when they do not exceed 4, and the names at the top; but when they are above that quantity, the points are to be taken from the right side column and the names at the bottom.

EXAMPLES.

EXAMPLES.

The log. sine of 3 points is - 9.744739

The log. tangent of 6 points is - 10.382776

TABLE XXIV.

Logarithms of Numbers.

This table contains the decimal part of the logarithms of numbers to six places of figures; but as in most of the calculations which occur in navigation five places are sufficient, it must be observed, that when the sixth figure is omitted, if it be 5 or above, the preceding or fifth is to be increased by 1; thus the logarithm .966986, when taken out to five places only, will be .96699.

Logarithms consist of two parts, which are separated by a point; that on the left hand of the point is called the *index*; the figures on the right hand is the *decimal part*; and as it is the latter only that is inserted in the table, the index must be supplied according to the following rules:

The index of a logarithm is always one less than the number of figures in the whole number; hence the index of 125 is 2, being one less than the number of figures contained in 125; also 2 is the index of 162.5: for although here are four figures, yet only three of them belong to the whole number, the .5 being a decimal figure. *If the natural number consists of decimal figures only, the index is 9 lessened by the number of cyphers before the first decimal figure*: thus the index of .0051 is 7, being 9 lessened by 2, the number of cyphers before the first decimal figure; the index of .03025 is 6, because there are three cyphers before the first decimal figure.

To find the Logarithm of a natural Number.

If the number consists of one or two figures only. Enter the first page of the table, and in one of the columns marked No. look for the given number; opposite to this, in the column marked Log. will be found the logarithm required, to which prefix the index according to the above directions: thus the logarithm of 56 is found to be 1.748188; the logarithm of 94 is 1.973128, and of .0025 is 7.397940.

If the number consists of three figures. Find the given number in the left hand column of the table, and opposite, in the column marked 0 at the top or bottom, will be the logarithm required, to which prefix the index as before: thus the log. of 295 is 2.469822; of 1.76 is 0.245513, and of .0542 is 8.733999.

When the number consists of four figures. Look for the first three figures in the left side column (without attending to the decimal point if there be any) and opposite to these, in the column marked with the fourth figure at the top or bottom, is the logarithm required: thus the logarithm of 1246 is 3.095518; of 17.95 is 1.254064, and of .2678 is 9.427811.

If the number consists of five or more figures. Find the logarithm of the first four figures, as before directed; then multiply the number found opposite in the right hand column under *diff.* (which is the difference between two adjacent logarithms) by the remaining figures; point off from the product as many figures from the right as the multiplier consists of, and those remaining being added to the logarithm of the first four figures, the sum will be the logarithm required, to which prefix the index. If the figures pointed off to the right hand exceed a half, the unit figure of the remainder

remainder is to be increased by one. Example. Required the logarithm of 25047. First look in the left side column for 250; opposite to this in the column with 4 at the top, is the logarithm 398634, and in the right side column the diff. 173; this multiplied by 7, the fifth figure, gives 1211; from which cut off the last figure, and the remainder 121 added to 398634 will give, with the index prefixed, 4.398755, the logarithm required. In this manner the logarithm of 598765 will be found 5.777256.

To find the natural Number corresponding to a given Logarithm.

If the number be required only to four figures. Look in the table for the logarithm nearest to that given, opposite to which will be found the first three figures in the left side column and the fourth figure at the top or bottom; the decimal point is then to be placed so that the whole number may contain *one figure more than that expressed by the index*. Suppose, for example, the natural number corresponding to the logarithm 2.326929 be required: the nearest logarithm to this is 326950, opposite to which is 212 in the left column, and 3 at the top, which placed after the first three figures, and the decimal point fixed according to the index, will give 212.3 the natural number required.

If the number be required to five or more figures. Find the logarithm next less to the given one, which will give the first four figures; then take the difference between that and the given logarithm, to which annex as many cyphers as there are figures wanted above four; divide this by the difference found opposite the nearest less logarithm, and the quotient will be the remaining figures required.

For example—To find the natural number corresponding to the logarithm 4.478309 to five figures: the nearest less logarithm is 478278, answering to the number 3008, and the difference between that and the given logarithm is 31; to this annex a cypher, and divide by the difference 145, the quotient will be 2; therefore the number required is 30082. In the same way the natural number corresponding to the logarithm 5.497646 to six figures is 314518.

When the given logarithm consists of only five places of figures, add a cypher to the fifth figure and proceed as before.

If the number required is to consist altogether of decimal figures, the same method must be used to obtain it as shewn above; only observe, that 9 cyphers lessened by the index are to be prefixed to the number found. Thus the number answering to the logarithm 7.819083 is .006593.

To find the arithmetical Complement of a Logarithm.

The arithmetical complement of a logarithm is the number it wants of 10.000000 or 20.000000 and the easiest way to find it is, beginning at the left hand, to subtract every figure from 9 except the last significant figure, which is to be taken from 10; but if the index exceed 9, it is to be taken from 19. Thus the arithmetical complement of 4.478309 is 5.521691 and of 10.935547 is 9.064453; it is frequently used in the rule of proportion and trigonometrical calculations to change subtractions into additions.

Here

Here follows a few examples to further illustrate the preceding rules.

	Nat. Num.		Logarithms.		Logarithms.		Nat. Num.
Given	56	to find	1.74819	Given	1.36977	to find	23.43
-	1.79	-	0.25285	-	2.45637	-	28.60
-	98.76	-	1.99458	-	3.56744	-	3693.5
-	596.84	-	2.775858	-	9.876542	-	.75256
-	.36875	-	9.566732	-	5.123562	-	132911
-	156795	-	5.195333	-	4.397625	-	24981.9

TABLE XXV.

Logarithmic Sines, Tangents, and Secants.

This table contains the logarithmic, or, as they are sometimes called, the artificial sines, tangents, and secants, to each degree and minute of the quadrant, with their complements or co-sines, co-tangents, and co-secants, to six places of figures besides the index; but it may be observed, as of the last table, that five places being generally sufficient in the common practice of navigation, when the sixth is omitted, and it is 5 or above, the preceding or fifth is to be increased by a unit.

To find the Logarithmic Sine, Co-Sine, &c. of any Number of Degrees and Minutes.

If the given degrees be under 45, they are to be taken from the top, and the minutes from the left side column, opposite to which in that column with the name of the logarithm at the top, will be found the required logarithm. But if the degrees be more than 45, they will be found at the bottom of the page, and the minutes in the right side column; likewise the name of the logarithm is to be taken from the bottom of the page.

When the given degrees exceed 90, they are to be subtracted from 180 degrees, and the logarithm of the remainder taken out as before. Or the logarithmic sine, tangent, &c. of degrees more than 90, is the logarithmic co-sine, co-tangent, &c. of their excess above 90 degrees.

EXAMPLES.

				log. to 6 places,	log. to 5 places,
Required the log. sine of	36 32	-	9.774729	-	9.77473
-	-	co-sine of	61 18	-	9.681443
-	-	tangent of	54 17	-	10.143263
-	-	co-tang. of	42 50	-	10.032877
-	-	secant of	19 27	-	10.025519
-	-	co-secant of	70 33	-	10.025519
-	-	sine of	108 36	}	9.976702
-	-	or sine of	71 24		
-	-	or co-sine of	18 36		

To find the Degrees and Minutes nearest corresponding to a given Logarithmic Sine, Co-sine, &c.

Look in the column marked at the top or bottom with the name of the given logarithm, and when the nearest to it is found, the corresponding degrees and minutes will be those required, observing that when the name is at the top of the column, the degrees are to be taken from the top and the minutes from the left side column, but if the name is at the bottom, the

corresponding degrees will be there likewise, and the minutes in the right side column.

EXAMPLES.

The degrees and minutes corresponding to the				
log. sine	9.265390	are	10°	37'
co-sine	9.528461		70	16
tangent	9.70156		26	42
secant	10.25413		56	9

The logarithmic sines, &c. taken out to degrees and minutes only are in general sufficiently accurate, but in some of the more rigid astronomical calculations, such as clearing the distance in lunar observations, it is frequently necessary to take them out to the nearest second: when this is the case they are to be found in the following manner:

To find the Logarithmic Sine, Tangent, Secant, &c. answering to a given Number of Degrees, Minutes and Seconds.

Find the log. sine, &c. answering to the given degrees and minutes as above, and take out from the proper column the difference of the adjacent logarithms to 100 seconds (marked at the top Diff. or D.); multiply this difference by the given seconds, and point off the two right hand figures in the product, then those remaining being added to the log. sine, tangent, or secant of the given degrees and minutes, or subtracted from the log. co-sine, co-tangent, or co-secant, will give the logarithm required.

The differences to the sines and co-sines are set down on the right of their respective columns: the differences to the tangents and co-tangents being the same are placed between them; and the differences to the secants and co-secants being the same as those to the co-sines and sines, are to be taken from the columns corresponding to the latter.

EXAMPLE I.

Required the Log. Sine of 32° 21' 45".

The logarithmic sine of 32° 21' is	-	-	-	-	9.728427
The diff. corresponding to the log. sine of the given degrees and minutes is 332; this multiplied by 45 (the number of seconds) pointing off two figures, is	-	-	-	-	+ 149
Sum is the log. sine required	-	-	-	-	9.728576

EXAMPLE II.

Required the Log. Co-sine of 71° 40' 25".

The logarithmic co-sine of 71° 40' is	-	-	-	-	9.497682
The diff. corresponding to the log. co-sine of the given degrees and minutes is 636; this multiplied by 25, gives	-	-	-	-	- 159
Remainder is the log. co-sine required	-	-	-	-	9.497523

EXAMPLE

EXAMPLE III.

Required the Log. Tangent of $56^{\circ} 42' 20''$.

The logarithmic tangent of $56^{\circ} 42'$ is	- - - -	10.182516
The corresponding diff. 459, multiplied by 20, gives	- - - -	+ 92
Sum gives the log. tangent required	- - - -	10.182608

EXAMPLE IV.

Required the Log. Co-secant of $65^{\circ} 18' 23''$.

The logarithmic co-secant of $65^{\circ} 18'$ is	- - - -	10.041671
The diff. corresponding to the sine of the given degrees and minutes is 97, which multiplied by 23, gives	- - - -	- 22
Remainder is the log. co-secant required	- - - -	10.041649

The logarithmic sines and tangents varying by great differences at the beginning of the quadrant, it has been thought proper for the sake of accuracy, to give them for the first and second degrees to every 10 seconds, with their mean differences in the right side column; when, therefore the log. sine or tangent of an arch less than 2 degrees is required, it is to be taken out to the next less tenth second, and the opposite difference multiplied by the odd seconds; then the product, cutting off one figure to the right, is to be added as before. As the sine and tangent of an arch is the co-sine and co-tangent of the complement of that arch, the latter may be found when above 88 degrees in a similar way, taking the degrees from the bottom and the minutes from the right side, and observing to subtract the proportional part.

EXAMPLE V.

Required the Log. Sine of $1^{\circ} 14' 43''$.

The logarithmic sine of $1^{\circ} 14' 40''$ is	- - - -	8.336819
The corresponding diff. 971, multiplied by 3, gives	- - - -	+ 291
Sum is the log. sine required	- - - -	8.337110

EXAMPLE VI.

Required the Log. Co-sine of $89^{\circ} 21' 25''$.

The logarithmic co-sine of $89^{\circ} 21' 20''$ is	- - - -	8.051054
The corresponding diff. 1880, multiplied by 5, gives	- - - -	- 940
Remainder is the log. co-sine required	- - - -	8.050114

To find the Degrees, Minutes, and Seconds, answering to a given Logarithmic Sine, Co-sine, &c.

Find the logarithm next less to the given one, if it be a sine, tangent or secant, or next greater if a co-sine, co-tangent, or co-secant, and note the corresponding degrees and minutes; then take the difference between the logarithm thus found and the given one, to which add two cyphers, and divide that number by the difference to 100'', the quotient will be the seconds to be annexed to the degrees and minutes before found.

EXAMPLE I.

Required the Degrees, Minutes, and Seconds, corresponding to the Log. Sine 9.695476.

The log. sine next less to that given is 9.695450, answering to $29^{\circ} 44'$; the difference between this logarithm and the given one is 26, which, with two cyphers added, makes 2600, and this divided by 368, the diff. to $100''$, gives the quotient $7''$ to be annexed to $29^{\circ} 44'$; hence $29^{\circ} 44' 7''$ are the required degrees, minutes and seconds.

EXAMPLE II.

Required the Degrees, Minutes, and Seconds, answering to the Log. Co-sine 9.566797.

The log. co-sine next greater to that given is 9.566951, to which answers $68^{\circ} 21'$; the difference between this logarithm and the given one is 154 which, with two cyphers added, makes 15400; this divided by 531, the diff. to $100''$, gives the quotient $29''$ to be annexed to $68^{\circ} 21'$; hence $68^{\circ} 21' 29''$ are the required degrees, minutes and seconds.

But if the logarithm next less or greater than the given one should be found in the first four pages of the table, it will point out the degrees, minutes, and nearest less tenth second; then to find the odd seconds, annex but one cypher to the difference found as before, and divide by the difference in the right side column.

EXAMPLE.

Required the Degrees, Minutes, and Seconds, answering to the Log. Sine 8.421604.

Here the next less logarithm is 8.421123, answering to $1^{\circ} 30' 40''$: now the difference between this log. and the given one, with one cypher annexed, is 4810, which divided by the diff. 799, gives $6''$; hence $1^{\circ} 30' 46''$ are the degrees, &c. required.

TABLE XXVI.

Natural Sines.

In this table the natural sines are exhibited to every degree and minute of the quadrant, and arranged so that the degrees corresponding to the sines are to be taken from the top of the page with their minutes in the left side columns, and the degrees answering to the co-sines from the bottom with their minutes in the right side columns; moreover, as they are given to six places of figures, the same rule with respect to the fifth figure must be observed when five only are required, as mentioned in the explanation to the two preceding tables.

The natural sine or co-sine of any number of degrees, &c. more than 90° , is the same as the natural sine or co-sine of its supplement, found by subtracting them from 180° ; or the natural sine or co-sine of an arch greater than 90° is the natural co-sine or sine of its excess above 90° .

To find the natural Sine or Co-sine of a given Number of Degrees, Minutes, and Seconds:

Or, to find the Degrees, Minutes, and Seconds, corresponding to a given natural Sine or Co-sine.

These are to be found as directed for the logarithmic sines, &c. except that the differences to 100" are to be taken from the bottom of that column containing the given degrees in the former case, or the nearest natural sine or co-sine in the latter.

EXAMPLE I.

Required the natural Sine of $32^{\circ} 21' 45''$, or its Supplement $147^{\circ} 38' 15''$

The natural sine of $32^{\circ} 21'$ is - - - - - 535090

The difference at the bottom of the column containing the natural sine of the given degrees and minutes is 409, this multiplied by 45, pointing off two figures in the product, is - } + 184

Sum is the natural sine required - - - - - 535274

EXAMPLE II.

Required the natural Co-sine of $71^{\circ} 40' 25''$, or $108^{\circ} 19' 35''$.

The natural co-sine of $71^{\circ} 40'$ is - - - - - 314545

The difference 460, multiplied by 25, pointing off two figures, is - 115

Remainder is the natural co-sine required - - - - - 314430

EXAMPLE III.

Required the Degrees, Minutes, and Seconds, answering to the natural Sine 495994.

The natural sine next less to that given is 495964, answering to $29^{\circ} 44'$; the difference between this natural sine and the given one is 30, to which two cyphers being added, and that divided by 422, the difference at the bottom of the column, gives the quotient $7''$ to be annexed to $29^{\circ} 44'$. Hence $29^{\circ} 44' 7''$, or its supplement $150^{\circ} 15' 53''$, are the degrees, &c. required.

EXAMPLE IV.

Required the Degrees, Minutes, and Seconds, answering to the natural Co-sine 368805.

The natural Co-sine next greater to that given is 368936, to which answers $68^{\circ} 21'$; the difference between this natural sine and the given one is 131, to which two cyphers being added, and that divided by 451, the difference found at the bottom of the column, gives the quotient $29''$. Hence $68^{\circ} 21' 29''$, or its supplement, $111^{\circ} 38' 31''$ are the degrees, &c. required.

To find the natural versed Sine of a given Number of Degrees, Minutes, and Seconds.

If the given arch be less than 90° , find its natural co-sine, which subtract from 1000000, and the remainder will be the natural versed sine required. But if the given arch exceed 90° , find the natural co-sine of its supplement,

EXPLANATION OF THE TABLES.

supplement, which add to 1000000, and the sum will be the natural versed sine required.

EXAMPLE I.

Required the natural versed Sine of $20^{\circ} 39'$.

The natural co-sine of $20^{\circ} 39'$ is 935752, which subtracted from 1000000, leaves 064248, the natural versed sine of $20^{\circ} 39'$.

EXAMPLE II.

Required the natural versed Sine of $146^{\circ} 38' 40''$.

The natural co-sine of $33^{\circ} 21' 20''$ (the supplement of $146^{\circ} 38' 40''$) is 835274, which added to 1000000, the sum 1835274 is the natural versed sine required.

To find the Degrees, &c. corresponding to a given natural versed Sine.

Take the difference between the given natural versed sine and 1000000, and the remainder will be a natural co-sine; the degrees, &c. corresponding to which, will be those required, if the given natural versed sine be less than 1000000, but if otherwise, it will be their supplement.

EXAMPLE I.

Required the Degrees, &c. answering to the natural versed sine 098965.

The above subtracted from 1000000, leaves 901035, which taken as a natural co-sine, corresponds to $25^{\circ} 42' 20''$.

EXAMPLE II.

Required the Degrees, &c. answering to the natural versed Sine 1160172.

Here 1000000 subtracted from the above, leaves 160172, which taken out as a natural co-sine, corresponds to $80^{\circ} 46' 59''$; therefore its supplement $99^{\circ} 13' 1''$ are the degrees, &c. required.

TABLES XXVII, XXVIII, XXIX.

Logarithmic Solar Tables.

These tables were first constructed by Mr. Douwes, Examiner of the Marine Cadets at Amsterdam, for the express purpose of finding the latitude by two altitudes of the sun and the elapsed time; but they are now applied to several other problems in nautical astronomy: they were formerly comprised in one table, but it has been thought more convenient to separate them, which we have here accordingly done. The logarithms in these tables being calculated to every 10 seconds of time, when the proportional part to odd seconds is wanted, it must be found by multiplying the difference between the logarithms of the next less and greater tenth second by the odd seconds, and pointing off the right hand figure: or if the time answering to a given log. is required to the nearest second, the difference between the logarithms next less and greater to the given one must be found, likewise the difference between the first of those two logarithms and the given one, to which a cypher being annexed, and this divided by the first difference, the quotient will be the odd seconds.

EXAMPLE

EXAMPLE I.

Required the Logarithm answering to the half elapsed Time 1 h. 29 m. 20 s.

In table XXVII. and in the page with 1 hour at the top, opposite 29 minutes, and in the column marked with 20^s at the top, will be found 0.42022, the logarithm required.

EXAMPLE II.

Required the Time answering to the Log. middle Time 4.92784.

The log. mid. time next less is (T. XXVIII.) 4.92765 4.92765
 - - - next greater is - 4.92833 given log. 4.92784

Diff. 68 Diff. 19

The difference between the preceding log. (corresponding to 1 h. 40 m. 10 s.) and the given one, with a cypher annexed, is 190; this divided by 68, the difference between the two nearest logarithms, gives the quotient 3^s. nearly: hence the middle time required is 1 h. 40 m. 13 s.

EXAMPLE III.

Required the Log. rising of 2 h. 55 m. 43 s.

The log. rising of 2 h. 55 m. 40 s. (Table XXIX.) is - 4.44662
 The difference between the above log. and the log rising of }
 2 h. 55 m. 50 s. is 78, which multiplied by 3, and pointing } + 23
 off one figure in the product, is - - - - -

Sum is the log. rising of 2 h. 55 m. 43 s. - - - - 4.44685

EXAMPLE IV.

Required the Time corresponding to the log. rising 4.73494.

The log. rising next less is 4.73462 4.73462
 - - next greater is 4.73514 given log. 4.73494

Diff. 52 Diff. 32

A cypher annexed to 32, and that divided by 52, the quotient is 6^s. this added to 4 h. 11 m. 10 s. the time answering to the next less log. gives 4 h. 11 m. 16 s. the time required.

TABLE XXX.

Correction of the Moon's apparent Altitude.

This table contains the correction to be added to the moon's apparent altitude in order to obtain the true, being the parallax in altitude lessened by refraction, the former of which makes the moon appear lower, and the latter higher, than her true place: this correction is likewise used in reducing the moon's apparent distance from the sun, or a star, to the true. The table is to be entered with the moon's apparent altitude to the nearest less tenth minute in the left side column, and the minutes of horizontal parallax at the top; the proportional part for the odd minutes of altitude may be found at the bottom of the page, observing that when the altitude is less than 10 degrees, to take the proportional part out with the nearest less tenth minute of altitude at the side and the odd minutes at the top.

The proportional part answering to seconds of parallax is to be taken from the right hand part of the table opposite the nearest less tenth second and under the unit seconds. If the moon's parallax is less than 54 minutes, the proportional part from the right hand side of the table, answering to the difference between the given horizontal parallax and 54 minutes, is to be subtracted from the correction corresponding to the given altitude and 54 minutes.

EXAMPLE I.

Required the Correction corresponding to the Moon's apparent Altitude $33^{\circ} 44'$ and horizontal Parallax $56' 57''$.

Correction to alt. $33^{\circ} 40'$ and horizontal par. $56'$	-	-	45' 11"
Proportional part to $4'$ of altitude	-	-	2"
- - - to $57''$ of hor. par.	-	-	48
			+ 46
Moon's correction required			45 57

EXAMPLE II.

Let the Moon's apparent Altitude be $48^{\circ} 36'$, and horizontal Parallax $53' 40''$, required the corresponding Correction.

Correction to alt. $48^{\circ} 30'$ and horizontal par. $54'$	-	-	34' 56"
Proportional part to $6'$ of altitude	-	-	4"
- - - to $20''$ of hor. par.	-	-	13
			- 17
Moon's correction required			34 39

EXAMPLE III.

Required the Correction corresponding to the Moon's apparent Altitude $7^{\circ} 36'$ and horizontal Parallax $60' 45''$.

Correction to altitude $7^{\circ} 30'$ and horizontal par. $60'$	-	-	52' 35"
Proportional part to $6'$ of altitude	-	-	+ 4
- - - to $45''$ of hor. par.	-	-	+ 45
Moon's correction required			53 24

TABLE XXXI.

Logarithmic Difference.

The logarithms in this table are applied in several methods of reducing the apparent to the true distance, particularly in those of Mr. Dunthorne's. They are to be taken out with the given degree of the moon's apparent altitude at the top, and the nearest less tenth second of horizontal parallax in the left side column; the proportional part for the minutes of altitude, which is subtractive, is found by multiplying the difference to 100 minutes, taken out of the right side column opposite the horizontal parallax, by the given minutes, and striking off two figures to the right; that answering to the odd seconds of parallax is found at the bottom part of the page under the given seconds, and is also subtractive. This logarithm is likewise to be further diminished by a number taken from the bottom of the page answering to the sun or star's altitude. The last correction may be more exactly taken from tables XXXII. XXXIII.

EXAMPLE

EXAMPLE.

Required the Logarithmic Difference corresponding to the Moon's apparent Altitude $45^{\circ} 9'$, the Sun's apparent altitude $10^{\circ} 14'$, and the Moon's horizontal Parallax $57' 34''$.

Log. diff. to moon's app. alt. 45° and hor. par. $57' 30''$	is	-	9.995045
The diff. 150, mult. by 9, gives the prop. part	-	13	
Prop. part to $4''$ of horizontal parallax	-	6	
Correction for sun's altitude 10°	-	7	
			26
Logarithmic difference required	-	-	9.995019

TABLES XXXII, XXXIII.

To correct the Logarithmic Difference.

These tables are intended to correct the logarithmic difference for the sun or stars apparent altitude, with which they are to be entered, and the corresponding number subtracted from the logarithmic difference.

TABLE XXXIV.

Proportional Logarithms.

These logarithms were first calculated by Dr. Maskelyne, in order to facilitate the operation of finding the apparent time at Greenwich, by comparing the observed distance between the moon and the sun, or a fixed star, when reduced to the true, with those set down in the Nautical Almanac, for every three hours of Greenwich time; and are likewise frequently applied in other calculations where sexagesimals are concerned. The table is to be entered either with degrees and minutes, or hours and minutes at the top and seconds in either side column. Thus the proportional logarithm of $0^{\circ} 15' 36''$, or 0 h. 15 m. 36 s. is 1.0621.

The proportional logarithm of any given number of seconds is found by subtracting its logarithm from 4.033424, which is the logarithm of the seconds in 3 hours or degrees.

TABLE XXXV.

To correct the apparent Distance.

This table contains a correction applied in reducing the apparent to the true distance by the approximate methods. It is to be entered with the distance at the top or bottom and the moon's correction in altitude and in distance (or second correction) alternately, in the side column; the difference between the number of seconds thus taken out is to be added to the corrected distance when less than 90° , or subtracted when above.

EXAMPLE.

Required the Correction corresponding to the Distance 70° , the Moon's Correction in Altitude $36''$, and the Moon's Correction in Distance $13''$.

In the column with 70° at the top, and opposite $36''$ in the side column is found $4''$; again in the same column opposite $13''$ in the side column

lumn stands 1"; the difference of these two numbers of seconds, viz. 3", is to be added to the corrected distance because it is less than 90°.

This table is somewhat altered from the original when the distance is above 90°, (the seconds being the complement to 20 of those formerly given) in order to adapt it to an easy and general method of clearing the distance, by Joseph de Mendoza Rios, Esq. F. R. S. When his method is used, the seconds are to be taken out with the apparent distance at the top or bottom, and the moon's correction and difference of corrections in the side column.

TABLE XXXVI.

Equations to equal Altitudes.

Observations of the sun taken when at equal altitudes, afford an easy and accurate method of ascertaining the time shewn by a watch at apparent noon, and from thence its error; but since the sun changes his declination more or less during the interval between the corresponding altitudes, the middle of the times by the watch when they were taken, will not be that shewn by it when the sun passes the meridian; and hence a correction, called the equation to equal altitudes, becomes necessary to be applied to the middle of the times, which may easily be computed by means of this table.

The table is divided into two parts, the arguments of which are the sun's longitude and the interval between the observations; the former to be taken from the top and the latter from the left side column, and when these cannot be exactly found, proportional parts must be employed.

The first part being found, its logarithm is to be added to the log. tangent of the given latitude, and the sum will be the logarithm of the reduced equation; which is additive or subtractive according to the signs at the top of the column when the given latitude is north, but the contrary to that expressed by the signs when the given latitude is south.

The second part is to be taken out in the same manner as the first, and is always additive or subtractive, as denoted by the signs at the top of the column from whence it was taken without any regard to the distinction of north or south latitude.

The method of using this Table will be best understood by the following example, in which the proportional parts are taken from Table XXXIX.

EXAMPLE.

Let the Sun's Longitude be VII signs 17° 45', the Latitude 57° 9' N. and the Interval 5 h. 17 m. required the Equation to equal Altitudes.

1st Part.		2d Part.	
Equation to VII signs 15° & interv. 5 hours	12 ^s .12	-	2 ^s .82
Prop. part to diff. .99 for sun's long 2° 45'	-.54	Diff. .01 for sun's long. 2° 45'	+.00
- - to diff. .12 for time - 17 m.	+.08	Diff. .07 for time - 17 m.	-.06
Equation to VII ^s 17° 45' & interv. 5 h. 17 m.		11.66	2.76
Lat. 57° 9'		Tang.	10.18997
Equat. first part - 11 ^s .66		Log.	1.06670
Red. equat. first part + 18.06		Log.	1.25667
- sec. part + 2.76			
Equation to equal alts. + 20.82 or 20 ^s . 49" additive, because both parts are so.			

But if we suppose the latitude to be South, then the first part being subtractive, the difference of the two parts, 15^s.30, will be the equation to equal altitudes, and subtractive because the greater part is so.

TABLE XXXVII.

To reduce the Equation of Time to any Time at Greenwich.

This Table is to be entered with the difference between the equations of time, taken from page II. of the Nautical Almanac, for the preceding and following noons at the top, and the time from the nearest noon at Greenwich in the side column; the corresponding correction is then to be applied to the equation of time for the nearest noon, as directed at the head of the table.

EXAMPLE I.

Required the Equation of Time on December 3d, 1805, at 8 h. 30 m. Greenwich Time.

	m.	s.
Equation of time for noon Dec. 3d by Nautical Almanac	-	9 57.2
Correction to difference 24.1, and time after noon 8 h. 30 m.	-	— 8.5
Reduced equation of time	-	9 48.7

EXAMPLE II.

Required the Equation of Time on April 8th, 1805, at 16 h. 35 m. at St. Helena, in Longitude 5° 43' West.

	h.	m.
Time at St. Helena	-	16 35
Longitude in time	-	+ 23 W.
		16 58
		24

Time before noon at Greenw. Apr. 9th 7 2

	m.	s.
Equation of time for noon April 9th, by Nautical Almanac	-	1 41
Correction to difference 17.1, and time before noon 7 h. 2 m.	-	+ 5
Reduced equation of time	-	1 46

TABLE XXXVIII.

To reduce the Sun's Longitude to Noon under a given Meridian.

This Table is to be entered with the sun's longitude for the noon on the given day, taken from page II. of the Nautical Almanac, in the top column, and with the ship's longitude in the side column; the corresponding correction is to be added to the sun's longitude as above, when the longitude of the ship is west, but subtracted when east.

EXAMPLE.

Required the Sun's Longitude at Noon on November 10th, 1805, in
Longitude 25° West.

Sun's longitude Nov. 10th, by Nautical Almanac	VII signs	17°	40'	50"
Correction for longitude 25° west	-	-	+	4 0
Sun's reduced longitude	-	VII signs	17	44 50

TABLE XXXIX.

Proportional Parts for Equations to equal Altitudes.

This Table is intended to facilitate the reduction of the equations to equal altitudes contained in Table XXXVI.; it is to be entered with the difference between the two adjacent equations at the top, and the excess of longitude or time above the nearest less to that given in the above Table in the side column; the proportional parts thus found are additive or subtractive according as the equations are increasing or decreasing. See the example to the explanation of Table XXXVI.

TABLE XL.

*Latitudes and Longitudes.**

This Table contains the latitudes and longitudes, from the meridian of Greenwich, of the principal ports, harbours, capes, shoals, rocks, &c. in the world, divided into different heads, and arranged according to the country, sea, or coast to which they belong: the manner of finding any required place, supposing its situation nearly known, is so obvious that it needs no further explanation.

The variation of the compass, as it stands at the present time, is occasionally inserted for the information of such persons as may not have an opportunity of finding it by observation.

TABLE XLI.

Times of High Water.

This table contains the times of high water at full and change, and the vertical rise of the tide at spring tides, the names of the places being alphabetically arranged.

* The Author, impressed with the importance of this Table, has used every exertion to render it as complete and correct as possible, by consulting the works of the best Navigators and Astronomers, at the same time comparing them with the most accurate charts and surveys, and by procuring the assistance of his nautical friends, from whom it has received considerable improvements; so that he flatters himself the present Table may be esteemed not only the most extensive, but likewise the most correct of any hitherto published: conscious, however, that errors must exist in a Table which depends on observation, (although he trusts they are few and inconsiderable) he takes this opportunity of earnestly requesting the intelligent Mariner to communicate to him any he may discover; for it is only by the accumulated knowledge of such men that we can hope to approach perfection on hydrographical subjects.

ASTRONOMICAL PROBLEMS,

FOR FINDING THE

LATITUDE AND LONGITUDE

AT SEA.*

PROBLEM I.

To find the Latitude of a Ship by two observed Altitudes of the Sun and the Time elapsed between the Observations, having also the Latitude by account, and the Sun's Declination when the greater Altitude was taken.

RULES.

1. To the log. secant of the latitude by account (XXV.) add the log. secant of the sun's declination; their sum, rejecting 20 from the index, is the *log. ratio*.

2. From the natural sine of the greater altitude (XXVI.) subtract the natural sine of the less altitude, and set the logarithm of their difference (XXIV.) under the *log. ratio*.

3. Take out the logarithm answering to half the elapsed time (XXVII.) and set it likewise under the *log. ratio*.

4. Add these three logarithms together, and find the middle time corresponding to the sum (XXVIII.); the difference between which and the half elapsed time, will be the time from noon when the greater altitude was observed.

5. From the log. rising answering to this time (XXIX.) subtract the *log. ratio*, and the remainder will be the logarithm of a natural number, (XXIV.) which being found and added to the natural sine of the greater altitude, their sum will be the natural sine of the meridian altitude.

* For the method of adjusting the instruments, of finding the latitude by a meridian altitude, and of taking a lunar observation, see "The Description and Use of Hadley's Quadrant and Sextant," by the Author.

6. Having the meridian altitude, the latitude is to be found in the usual manner.

7. If the latitude thus found differs considerably from the latitude by account, the operation is to be repeated; using the computed latitude instead of that by account, until the latitude last found agrees nearly with the latitude used in the computation.

NOTE.—The observations must be taken between nine o'clock in the forenoon and three in the afternoon. If both observations be in the forenoon, or both in the afternoon, the elapsed time must not be less than the time from noon when the greater altitude is taken. If one observation be in the forenoon, and the other in the afternoon, the interval must not exceed four hours and a half; and in all cases, the nearer the greater altitude is to noon the better.

If the sun's meridian zenith distance be less than the latitude, the limitations are still more contracted. If the latitude be double the meridian zenith distance, the observations must be taken between half past nine in the forenoon, and half past two in the afternoon, and the interval must not exceed three hours and a half. The observations must be taken still nearer to noon, if the latitude exceed the meridian zenith distance in a greater proportion.

EXAMPLE I.

On February 24th, 1805, in latitude $49^{\circ} 36'$ N. by account, at 0 h. 33 m. P. M. the altitude of the sun's lower limb was $28^{\circ} 53'$, and at 2 h. 43 m. P. M. it was $19^{\circ} 44'$; the height of the eye being 14 feet; required the true latitude.

First observed altitude	28 53	Second observed altitude	19 44
Semidiameter + 16'	+ 12	Semidiameter + 16'	+ 12
Dip - 4		Dip - 4	
	29 5		19 56
Refraction - -	- 2	Refraction - -	- 3
True altitude	29 3	True altitude	19 53

Aug 10 - 1891

Latitude - 51 0 N.

In the preceding example both observations were supposed to be taken in the same place; but as that is seldom the case, it will be necessary, when the ship is making much way, and the elapsed time is considerable, to correct the less altitude in order to find what it would have been, had it been taken at the place where the greater altitude was observed; which is to be done as follows:

If the less altitude be observed in the forenoon, the correction is to be added to it, if the above angle is less than 8 points, but when it is more, to be subtracted.

If the less altitude be observed in the afternoon, the correction is to be subtracted if the angle is less than 8 points, but when greater, it is to be added to the less altitude.

The less altitude being thus corrected, proceed according to the rule, and the result will be the latitude of the ship when the greater altitude was observed.

EXAMPLE II.

PROBLEM II.

To find the apparent Time at the Ship by an Altitude of the Sun.

RULES.

1. To the observed altitude add the difference between the semidiameter (from page III. of the Nautical Almanac) and the dip (V.); the sum will be the apparent altitude; from this take the difference between the refraction and parallax (IV. VI.), the remainder will be the sun's true altitude.

2. Take out the sun's declination for the nearest noon from page II. in the Nautical Almanac, and correct it for longitude and time (XXI.)

3. If the sun's declination and co-latitude of the ship be one north and the other south, take their difference; but if they be both north or both south, take their sum for the meridian altitude. If that sum exceed 90° , take it from 180° .

4. From the natural sine of the sun's meridian altitude (XXVI) take the natural sine of the sun's true altitude at the time of observation; then add together

The log. co-secant of the co-latitude (XXV.)

The log. secant of the declination, and

The log. of the difference of the natural sines (XXIV.)

The sum of these three logs. rejecting tens in the Index, being found in the Table of Rising, (XXIX.) the time corresponding to it will be the apparent time from the nearest noon, consequently if the observation be made in the morning, the time thus found must be taken from 24 hours to obtain the apparent time from the preceding noon.

NOTE.—The observations should be taken when the sun is at least two or three hours distant from the meridian, and the nearer it is to the east or west points of the horizon the better, because then the change of altitude is quickest, and an error of a few miles in latitude will not affect the time.

It will be proper to observe several altitudes, noting the times by the watch when each is observed, and to use the means of the sets, which are found by adding the sets together and dividing their sum by the number that are taken.

EXAMPLE I.

June 5th, 1805, the following observations were made of the sun's lower limb, in latitude $31^\circ 15' N.$ and longitude by account $36^\circ 50' W.$ the height of the eye being 20 feet; required the apparent time, and from thence the error of the watch.

PROBLEM III.

To find the apparent Time at the Ship by an Altitude of a Star.

RULES.

1. From the observed altitude subtract the dip and refraction (V. IV.), the remainder will be the star's true altitude.

2. Reduce the star's right ascension and declination (XV.), and the sun's right ascension (taken from page II. of the Nautical Almanac) to the time of observation (XXII.)

3. Proceed as with the sun in the last problem to find the time corresponding to the logarithm rising (XXIX.) which will be the star's distance from the meridian; this being added to the star's right ascension if the star is observed to the westward, or subtracted from it when observed to the eastward, the sum or remainder will be the right ascension of the meridian.

4. From the right ascension of the meridian (increased by 24 hours if necessary) subtract the sun's reduced right ascension, and the remainder will be the apparent time of observation at the ship.

NOTE.—If the time at the ship is not nearly known, then from the right ascension of the meridian subtract the sun's right ascension for the nearest noon, the remainder will be the time at the ship nearly; to this add the correction for the time from noon (XXII.) if the observation be taken in the morning; but subtract it if taken in the afternoon; likewise add the correction for longitude if the longitude be east, or subtract it if west, and the result will be the apparent time.

EXAMPLE.

January 5th, 1805, latitude $18^{\circ} 22'$ N. and longitude by account $88^{\circ} 15'$ E. the following altitudes of the star Procyon were taken when westward of the meridian: the observer's eye being 20 feet above the surface of the sea: required the apparent time and error of the watch.

PROBLEM IV.

Given the apparent Time, and the Ship's Place, to find the true and apparent Altitudes.

RULES.

1. Find the meridian distance of the given object, which, if it be the sun, is the apparent time from noon; but if the object be the moon, or a star, then add the sun's right ascension to the apparent time; their sum will be the right ascension of the meridian; the difference between which and the right ascension of the object, will be its meridian distance.

2. Add together the log. rising of the meridian distance (XXIX.)

the log. co-sine of the latitude (XXV.)

and the log. co-sine of the declination;

the natural number corresponding to the sum of these three logarithms (rejecting the tens in the Index) (XXIV.) being found, and subtracted from the natural sine (XXVI.) of the sum of the co-latitude and declination when they are of the same name, or their difference when of contrary names, will give the natural sine of the true altitude.

3. If the object be the sun, the difference of his refraction and parallax (IV. VI.) added to the true altitude, will give the apparent altitude: if it be a star, the apparent altitude is found by adding the refraction to its true altitude; but when the true altitude of the moon is to be reduced to its apparent altitude, the correction taken from Table XXX. with the true altitude and horizontal parallax is to be subtracted from the true altitude; and if greater accuracy is required, this correction must be taken out a second time with the apparent altitude just found, and applied instead of the former.

NOTE.—The right ascension and declination of the sun and moon are to be taken from the Nautical Almanac, and reduced to the time of observation.

EXAMPLE I.

Required the true and apparent Altitudes of the Sun on June 5th, 1805, in Latitude $31^{\circ} 15' N.$ and Longitude $36^{\circ} 50' W.$ at 4 h. 49 m. 40 s.

But if greater accuracy be required, the moon's correction must be again taken out with the above apparent altitude, which will give it $48' 14''$; and this subtracted from the true altitude $30^{\circ} 29' 27''$, will give the apparent altitude $29^{\circ} 41' 13''$.

PROBLEM V.

To find the Longitude by a Lunar Observation.

RULES.

To find the apparent Altitudes and Distance.

1. Turn the ship's longitude by account into time (XIX.) and add it to the time at the ship if it be west, but subtract it if east; the sum or remainder will be the time at Greenwich nearly.

2. From page VII. in the Nautical Almanac take out the moon's horizontal parallax and semidiameter, and reduce them to Greenwich time;* from Table VII. take a number of seconds answering to the observed altitude, which add to the moon's reduced semidiameter.

3. If the moon's lower limb be observed, add the semidiameter to the observed altitude, but, if the upper limb be taken, subtract it; then subtract the dip of the horizon (V.); and the result will be the moon's apparent altitude.

4. Then, *if the sun be observed*, to the observed altitude of the lower limb add the semidiameter (taken from page III. of the Nautical Almanac) and subtract the dip to give the sun's apparent altitude.

5. To the observed distance add the semidiameters of the sun and moon, the sum will be the apparent distance.

6. But, *if a star be observed*, from its observed altitude subtract the dip, and the remainder will be the star's apparent altitude.

7. To the observed distance of the moon and star add the moon's semidiameter, if the nearest limb was taken, but subtract it if the farthest limb was observed, the sum or difference will be the apparent distance.

To find the true Distance.

METHOD I.

1. To the correction of the moon's altitude (XXX.) add the correction of the sun or star's altitude;† their sum, added to the difference of the apparent altitudes when the moon's altitude is greater, or subtracted from it when the moon's altitude is less than the sun or star's, will give the difference of their true altitudes.

2 From the natural co-sine of the difference of the apparent altitudes (XXVI.) subtract the natural co-sine of the apparent distance, when the apparent distance is less than 90° , but when it is greater, add together the natural co-sines, and to the logarithm of this sum or remainder (XXIV.)

* The moon's horizontal parallax and semidiameter are reduced to the time of observation at Greenwich thus: take them out for the nearest noon or midnight both before and after Greenwich time, then say, as 12 hours is to the difference in 12 hours, so is the time at Greenwich, since the preceding noon or midnight, to a proportional part, which being added to or subtracted from the horizontal parallax or semidiameter at the preceding noon or midnight, according as it is increasing or decreasing, will give them reduced to the time of observation.

† The difference between the refraction and parallax of the sun in altitude (IV. VI.) is the sun's correction. The refraction of the star in altitude is its correction.

add the logarithmic difference (XXXI.): then the difference between the natural number of this sum and the natural co-sine of the difference of the true altitudes, will be the natural co-sine of the true distance when the natural number is less than the natural co-sine of the difference of the true altitudes, otherwise the remainder will be the natural co sine of the supplement of the true distance, or the natural sine of the excess of the true distance above 90° .

METHOD II.

1. To the sum of the apparent altitudes add the difference of the correction of the moon's altitude (XXX.) and of the sun or star's altitude,* which will give the sum of the true altitudes, of which take half.

2. Add together the apparent altitudes and apparent distance, and find the difference between half this sum and the apparent distance.

3. To the log. co-sines of the half sum and difference (XXV.) add the logarithmic difference (XXXI.), and half the sum of these three logs. will be the log. sine of an arch.

4. Add together the log. co-sines of the sum and difference of the arch, and half the sum of the true altitudes; then will half the sum of these two logarithms be the log. sine of half the true distance.

NOTE.—In the preceding methods, it may be observed, that the seconds of the apparent distance may be omitted until the operation is finished, and then they are to be added to the computed distance. If the sum of the apparent distance and altitudes should have an odd digit in the units place of the minutes, the minutes in the distance may be increased by a unit, and, in this case, what the given number of seconds wants of $60''$ are to be subtracted from the computed distance.

METHOD III.

1. Add the sun or star's and the moon's apparent altitudes together, and take half the sum; subtract the less from the greater, and take half the difference; then add together

The log. co-tangent of half the sum (XXV.)

The log. tangent of half the difference, and

The log. co-tangent of half the apparent distance;

their sum, rejecting the tens in the Index, will be the log. tangent of an arch, which call A.

2. When the sun or star's altitude is greater than the moon's, take the difference between the arch A. and half the apparent distance, but if less, take their sum; then add together

The log. co-tangent of this sum or difference,

The log. co-tangent of the sun or star's apparent altitude, and

The proportional logarithm (XXXIV.) of the sun or star's correction;*

their sum, rejecting the tens in the Index, will be the proportional logarithm of the first correction.

* See Note at bottom of page XXXVIII.

Or the refraction answering to the complement of the above mentioned sum or difference, will be the first correction nearly.

3. If the sum of the arch A. and half the apparent distance, was taken in the preceding article, now take their difference, but if their difference was then taken, now take their sum; then add together

The log. co-tangent of this sum or difference,

The log. co-tangent of the moon's apparent altitude, and

The proportional logarithm of the moon's correction (XXX.)
their sum, rejecting the tens in the Index, will be the proportional logarithm of the second correction.

4. When the arch A. is less than half the apparent distance, the first correction must be added to, and the second correction subtracted from the apparent distance; but when the arch A is greater, both the first and second corrections are to be added to the apparent distance if the moon's altitude is the greater; but when the moon's altitude is the less, they are both to be subtracted from it to give the corrected distance.

5. Enter Table XXXV. with the corrected distance at the top or bottom, and the moon's correction and second correction alternately in the side column; the difference between the number of seconds thus taken out being added to the corrected distance when it is less than 90° , or subtracted from it when above, will give the true distance.

METHOD IV.

1. Add together the apparent distance and apparent altitudes, and take half their sum: the difference between the half sum and the sun or star's apparent altitude call the first remainder; and the difference between the half sum and the moon's apparent altitude call the second remainder.

2. Add together the log sine of the apparent distance,
the log. co-sine of the moon's apparent altitude,
the log. secant of the half sum,
the log. co-secant of the first remainder,
the proportional log. of the moon's correction (XXX.)
and the constant logarithm 9.6990;
their sum, rejecting the tens in the Index, will be the proportional logarithm of the first correction.

3. Add together the log. sine of the apparent distance (already found)
the log. co-sine of the sun or star's apparent altitude,
the log. secant of the half sum (already found)
the log. co secant of the second remainder,
the proportional log. of the sun or star's correction,*
and the constant logarithm 9.6990:
their sum, rejecting the tens in the Index, will be the proportional logarithm of the second correction.

4. The difference between the first correction and the correction of the moon's altitude, call the difference of corrections.

Enter Table XXXV. with the apparent distance at the top and the moon's correction in the side column, the corresponding number will be

* See note at bottom of page XXXVIII.

the third correction: in the same column, and opposite the difference of corrections, will be found the fourth correction.

5. Subtract the sum of the moon's correction, and the second and fourth corrections from the apparent distance; to the remainder add the sun or star's correction, and the first and third correction; their sum will be the true distance.

To find the Longitude of the Ship.

1. Among the true distances of the moon's center from the sun or fixed stars, set down in pages VIII. IX. X. and XI. of the Nautical Almanac, find those two distances which are next less and greater than the true distance found by the observation, which place under it; take the difference between the true distance, and the first of these two distances, also the difference between the two distances; subtract the proportional logarithm of the second difference from the proportional logarithm of the first difference, and the remainder will be the proportional logarithm of a portion of time, which added to the time that the first of the two distances, taken from the Almanac, was computed for, the sum will be the apparent time at Greenwich.

2. Take the difference between the apparent time at Greenwich and the apparent time at the Ship,* and convert it into degrees and minutes (XIX.) and it will give the true longitude of the ship; east, if the time of the ship be greater than the time at Greenwich, (reckoned from the same noon) but west if the time at the ship be less than the time at Greenwich.

EXAMPLE I.

On June 5th, 1805, in longitude $37^{\circ} 10' W.$ by account, the following sets of observations were taken, the height of the eye being 20 feet, and the errors of the watch (see Example I. page XXXIII.) and instruments previously ascertained; required the true longitude of the ship.

* If the sun, or the star from which the moon's distance is computed, be far enough from the meridian when the distance was observed, the time at the ship is to be inferred from its altitude by Problem II. or III.; but if the object is too near the meridian, or the altitude taken with the distance cannot well be depended on, (although it may be sufficiently exact for clearing the distance) the time at the ship, and thence the error of the watch, must be found either before or after the distance is taken, and the error applied to the mean of the times, given by the watch, when the distance is observed (as in the first example); and it must be understood that in this case the longitude deduced from the lunar observation will be the meridian the ship was under when the error of the watch was ascertained.

PROBLEM VI.

To find the Longitude by a Chronometer or Time-keeper.

RULES.

1. Take several altitudes of the sun, or a star, when it is at least two or three hours from the meridian, and note the times by the Chronometer when they were observed, of which take the means.

2. To the mean of the times add what the Chronometer was too slow, or subtract what it was too fast for mean time at the place where the rate was ascertained; then multiply the daily rate by the number of days and parts of a day that have elapsed since it was determined, the product of which, added to the above sum or remainder, if the Chronometer is losing, or subtracted from it if gaining, the result will be the mean time at the place where the rate was ascertained, to which add the longitude of the place in time if it be west, or subtract it if east, and the sum or remainder will be the mean time at Greenwich.

* The time at the ship is here found with the latitude, the sun's true altitude and declination by Problem II page xxxiii.

3. With the latitude, true altitude, and declination find the apparent time as in Problem II. or III. to which apply the equation of time, (found as directed in the explanation of Table XXXVII.) by addition or subtraction, according to its title at the head of the column from whence it is taken in the Nautical Almanac; hence will be found the mean time at the ship; the difference between which and the mean time at Greenwich will give the ship's longitude; east if the time at the ship be greater, or west if it be less than the time at Greenwich.

EXAMPLE I.

On June 23d, 1805, in latitude $10^{\circ} 4' S.$ the following altitudes of the Sun's lower limb were observed with their correspondent times by a Chronometer, whose daily gain had been settled at noon on April 21st at 2.1s per day, at which time it was 2h. 31m. 45s. too fast for Greenwich time, the height of the eye being 20 feet; required the true longitude of the ship.

For reducing Moon's Declination to any given Meridian, and to any Time under that Meridian.

When γ 's dec. { Add in W. long. } Add corr. | When γ 's dec. { Sub. in W. long. } Sub. corr.
is increasing { Sub. in E. long. } for time. | is decreasing { Add in E. long. } for time.

Long.	Variation of the Moon's Declination in twelve Hours.														Time from noon or midni.

Second Part.

[illegible]

To reduce the EQUATION OF TIME to any given Time from Noon at Greenwich.

When Eq. of time { Add after noon is increasing { Sub. before noon }		When Eq. of time { Sub. after noon. is decreasing { Add before noon.															
Time fr. noon.		Daily Variation.

LATITUDES AND LONGITUDES

Of the principal Ports, Harbours, Capes, Shoals, Rocks, &c. in the WORLD, founded on several thousand observations made by the most eminent ASTRONOMERS and NAVIGATORS, compared with the latest and most accurate CHARTS and SURVEYS; to which is occasionally added the Variation of the Compass.

The Longitudes are reckoned from the Meridian of Greenwich.
